Importing, working with, and exploring data Week 2, Lecture 04:

Richard E.W. Berl Spring 2019

Loading data

Manipulating data

Subsetting

Subsetting is one of the most common tasks when you're dealing with data. There are multiple ways to subset data, specifically when it is in a data frame.

Using references

The first you've already done: just select the rows or columns you want.

horseKicks[,c(1:2)]

```
## 12 1886
## 13 1887
             1
## 14 1888
## 15 1889
## 16 1890
## 17 1891
## 18 1892
## 19 1893
             0
## 20 1894
You can do so by name:
horseKicks[c(1,5:10),c("C1","C2","C3")]
##
      C1 C2 C3
## 1
       0
       0
## 5
          0
              1
## 6
       3
           2
              1
## 7
       0
          0
              2
## 8
       2
          0
              0
## 9
       0
              2
           1
```

You can also exclude rows or columns you **don't** want by putting a – before the vector. Here I use a sequence to exclude odd years:

horseKicks[-seq(1, nrow(horseKicks), 2),]

```
Year GC C1 C2 C3 C4 C5 C6 C7 C8 C9 C10 C11 C14 C15
## 2
       1876
                  0
                     0
                                0
                                    0
                                        0
                                           0
                                               0
                                                    0
                                                         0
                         0
                             1
                                                              1
                                                                   1

                                            1
                                                    0
                                                         1
                                                              1
                                                                   0
                             1
                                1
## 20 1894
              1
                  0
                     0
                         0
                             0
                                0
                                    0
                                                                   0
```

Using conditionals

Remember which()? You already used it for subsetting. If we just want the rows that match a certain condition, we put the statement in the row reference spot:

gombe[which(gombe\$innov > 6),]

```

```

The first returns the row indices that match that condition, and the second returns a logical vector for every row in the data frame. Remember that either can be used to reference a data frame.

You can get rows that must match more than one condition with the & operator:

gombe[gombe\$innov > 6 & gombe\$sex == 1,]

```

```

You can also use (or make) another vector that contains the names of the columns you want, and keep only the values that match. This uses the useful operator %in%, which asks "Is X %in% Y?" and returns TRUE or FALSE for each element in X.

```
varsToKeep = c("chimpcode", "dom", "soc")
head(gombe[,colnames(gombe) %in% varsToKeep])
##
     chimpcode
                     dom

## 6
```

Using subset()

Finally, sometimes the most straightforward way is to use the subset() function. You can pull up its help documentation and have a look at the syntax.

```
subset(hairEyeColor, Hair == "Black" & Eye == "Blue")
## Hair Eye Sex Freq
## 5 Black Blue Male 11
## 21 Black Blue Female 9
```

Notice that I didn't specify the names of the arguments here (x=, subset=). If you enter your arguments in the same order they appear in the function definition, you don't have to specify which is which. For functions like subset, it's easy to tell what each argument is referring to (and x=Hair ==... would look really confusing). Just make sure you're entering them in the right order, or you may get unexpected results.

Remember you need to assign your subset if you want to keep it! Otherwise your data frame is unchanged.

You should always keep your original data frame and assign subsets to new data frames, so that you can always go back and see the original or subset it differently.

Cleaning data

Tidy data

Three rules:

- 1. Each variable forms a column.
- 2. Each observation forms a row.
- 3. Each type of observational unit forms a table.

Visit: https://opendata.fcgov.com/Neighborhood-Livability-and-Social-Health/Fort-Collins-Shelter-Service-Data/u8nn-nj59

On the top right, click the "Export" button and then the "CSV" button to download the data. Place it in your class /data directory.

Read it into R:

```
focoShelter = read.csv(file="./data/Fort_Collins_Shelter_Service_Data.csv", header=TRUE)
```

Let's take a look at the data.

head(focoShelter)

```

So... are these data "tidy"?

No. Why not?

We've got variables spread across multiple columns. One variable is whether it was a Rescue Mission shelter or a Catholic Charities shelter. Another is whether it is referring to men, women, families, or all. The other variables are split apart by each of these.

So how do we fix it? Let's consult the Cheat Sheet.

Then we need to load the tidyr package. If you haven't installed the tidyverse package (which includes tidyr), you can do so now, or just install tidyr alone.

library(tidyr)

First, let's get rid of the last two columns since we don't need them.

```
focoShelter = focoShelter[,-c(12:13)]
```

Right now our data are in what's called **wide** format. It's called this because all of your variables are columns, so if you have a lot of variables then your data frame will stretch out horizontally. Because of Tidy Data Rule #1, most "tidy" data will be wide.

Our goal is to get these data cleaned up and back into the wide format. But first we have to change it to tall format to split some of our variables apart, and then convert it back to wide.

To get our data into the **tall** format, we use the **gather()** function from the Cheat Sheet. Prior to the **tidyr** package being developed, this was called "melting" (by using the **melt()** function from **reshape2**).

```
focoShelterTidy = gather(focoShelter, "variable", "value", 2:11)
```

We can use unique() to see all the unique values of the variable variable, to make sure all of our columns made it.

unique(focoShelterTidy\$variable)

```
[1] "Rescue.Mission.Total.Served...Men"
##
    [2] "Rescue.Mission.Total.Served...Women"
##
   [3] "Rescue.Mission...of.Nights.with.Turnaways...Men"
   [4] "Rescue.Mission...of.Nights.with.Turnaways...Women"
##
   [5] "Rescue.Mission...Total...Turned.Away"
##
   [6] "Catholic.Charities.Total.Served...Men"
##
##
   [7] "Catholic.Charities.Total.Served...Women"
  [8] "Catholic.Charities.Total.Served...Families"
  [9] "Catholic.Charities...of.Nights.with.Turnaways"
## [10] "Catholic.Charities...Total...Turned.Away"
```

They did!

But we can see from our variable names that not all of them are split by "Men," "Women," and "Families." Some of them represent total numbers.

So, for our next step, let's split our data frame into two: one that contains only the "Men," "Women," and "Families" variables; and another that has all the others.

One way we can do this is to use grepl(), the logical version of the grep() function, which searches for partial character matches. We use it to search for any values of variable that contain the text "Men," "Women," or "Families," and then we subset the data frame to the rows that contain any of them (with the | "OR" operator).

For our second subset that contains all the other rows, all we have to do is put a ! before the grepl() functions to negate the logical vector that comes out of it (all "TRUE"s become "FALSE" and vice versa). This gives us the complementary set of rows to what we subset before.

Now let's make sure both of our subsets add up to the whole.

```
nrow(focoShelterTidy)
## [1] 220
nrow(focoShelterMWF) + nrow(focoShelterNot)
## [1] 220
```

And we can take a look at our "MWF" data frame.

head(focoShelterMWF)

```
##
                     Month
                                                     variable value
## 1 06/01/2017 12:00:00 AM Rescue.Mission.Total.Served...Men 1548
## 2 07/01/2017 12:00:00 AM Rescue.Mission.Total.Served...Men 1616
## 3 08/01/2017 12:00:00 AM Rescue.Mission.Total.Served...Men 1616
## 4 09/01/2017 12:00:00 AM Rescue.Mission.Total.Served...Men 1650
## 5 10/01/2017 12:00:00 AM Rescue.Mission.Total.Served...Men 2045
## 6 11/01/2017 12:00:00 AM Rescue.Mission.Total.Served...Men 2167
str(focoShelterMWF)
## 'data.frame':
                   154 obs. of 3 variables:
             : Factor w/ 22 levels "01/01/2018 12:00:00 AM",...: 9 11 13 15 17 19 21 1 3 5 ...
## $ variable: chr "Rescue.Mission.Total.Served...Men" "Rescue.Mission.Total.Served...Men" "Rescue.Mi
   $ value
             : int 1548 1616 1616 1650 2045 2167 2036 2248 2023 1909 ...
colnames(focoShelterMWF)
```

[1] "Month" "variable" "value"

Our next task is to split the "Sex" element off of each variable. We can do this easily by using the "..." part of each variable name just before the sex it's referencing. The trouble is that some of the variable names have another "..." earlier in the character string and some don't.

One way to deal with this would be to just rename the variables (you could use recode() or gsub()) to make them easier to split.

Here, I use a nasty bit of regex ("regular expressions") to tell the function that I want it to separate based on the last occurrence of "..." for each variable name.

Some functions, like grep1() above, use regex but also allow you to just type in the match you want (with the fixed=TRUE argument). Unfortunately, separate() doesn't, but will often still work with plain text.

After doing that, we want to merge our two subset data frames back together. But to do that, they both need to have the same structure: the same columns in the same order.

So, for the "Not" data frame, we need to add the "Sex" column and, when we do, we can assign a value of "Total" for all of those variables, since they all refer to the total number of people served regardless of sex or gender.

Then, we reorder the columns to match the "MWF" data frame.

```
focoShelterNot$Sex = "Total"
focoShelterNot = focoShelterNot[,c(1,2,4,3)]
```

Let's check them out to make sure they look compatible.

head(focoShelterMWF)

```
## 1 06/01/2017 12:00:00 AM Rescue.Mission.Total.Served Men 1548
## 2 07/01/2017 12:00:00 AM Rescue.Mission.Total.Served Men 1616
## 3 08/01/2017 12:00:00 AM Rescue.Mission.Total.Served Men 1616
## 4 09/01/2017 12:00:00 AM Rescue.Mission.Total.Served Men 1650
## 5 10/01/2017 12:00:00 AM Rescue.Mission.Total.Served Men 2045
## 6 11/01/2017 12:00:00 AM Rescue.Mission.Total.Served Men 2167
```

```
head(focoShelterNot)
```

```
## 89 06/01/2017 12:00:00 AM Rescue.Mission...Total...Turned.Away Total 41
## 90 07/01/2017 12:00:00 AM Rescue.Mission...Total...Turned.Away Total 10
## 91 08/01/2017 12:00:00 AM Rescue.Mission...Total...Turned.Away Total 37
## 92 09/01/2017 12:00:00 AM Rescue.Mission...Total...Turned.Away Total 21
## 93 10/01/2017 12:00:00 AM Rescue.Mission...Total...Turned.Away Total 55
## 94 11/01/2017 12:00:00 AM Rescue.Mission...Total...Turned.Away Total 15
```

They do. So now we can use rbind() to join them together row-wise (the second data frame underneath the first). If we needed to join extra columns, we could use cbind(), or there are a number of dplyr solutions for joining variables from different data sets on the Cheat Sheet.

focoShelterTidy = rbind(focoShelterMWF, focoShelterNot)
str(focoShelterTidy)

```
## 'data.frame': 220 obs. of 4 variables:
## $ Month : Factor w/ 22 levels "01/01/2018 12:00:00 AM",..: 9 11 13 15 17 19 21 1 3 5 ...
## $ variable: chr "Rescue.Mission.Total.Served" "Rescue.Mission.Total.Served" "Rescue.Mission.Total.Served" "Rescue.Mission.Total."
## $ Sex : chr "Men" "Men" "Men" ...
## $ value : int 1548 1616 1616 1650 2045 2167 2036 2248 2023 1909 ...
```

Looks good. Our last step is to convert it all back to wide format again.

focoShelterTidy = spread(focoShelterTidy, variable, value)
head(focoShelterTidy)

```

Our data are now (mostly) tidy! (Note: We actually still have one more variable to split off: the type of shelter being Rescue Mission or Catholic Charities, but we'll leave it for now.)

There are a couple of final details we could take care of, though. Our Month variable and Sex variable have gotten out of order compared to the original data frame. We can fix them by reassigning them as factors and specifying the order of the levels. For Month, we can use the order given in the original data frame. For Sex we can write it out manually.

Then, we sort the data frame by those two columns. One way, used below, is to use the with() and order() functions, but there are others.

```
focoShelterTidy$Month = factor(focoShelterTidy$Month,
                                levels=as.character(focoShelter$Month))
focoShelterTidy$Sex = factor(focoShelterTidy$Sex,
                              levels=c("Men","Women","Families","Total"))
focoShelterTidy = focoShelterTidy[with(focoShelterTidy, order(Month, Sex)),]
head(focoShelterTidy)

There is more we could do to these data, but we will leave it for now. For one, we can see there are a lot of missing data values. This is just because none of the variables had all of those levels defined in the first place. It would probably make sense for us to sum the other values of Sex to the level Total for variables that don't have Total defined. That way we could use that level for analysis, and look at the other levels if we wanted finer breakdowns by Men, Women, and Families for the variables that have them.

Problems with data

Missing data

36

Finding missing data

As we have seen, some data sets can have a lot of missing data, and this can be a problem when we want to run analyses.

For another example, we can load the built-in airquality data set.

```
data("airquality")
head(airquality)
```

```
Ozone Solar.R Wind Temp Month Day
##
## 1
         41

                              66
                                          6
```

We can see right away that airquality has some NA values.

A quick way to see how many missing values our data has is to use the summary() function, which lists the number of NAs in each column below some summary statistics.

summary(airquality)

```

There are other ways to find missing values in a data set. For specific columns, we can subset using the is.na() function, which returns TRUE if it finds an NA value.

airquality[is.na(airquality\$0zone),]

If we want to see the rows that have ANY missing values across all columns, we can use rowSums() with is.na() to return rows where at least one NA value exists.

airquality[rowSums(is.na(airquality)) > 0,]

##		Ozone	Solar.R	Wind	Temp	Month	Day

##	150	NA	145	13.2	77	9	27

With smaller data sets, it can also be easy to pick out NA values by scanning the data frame in a spreadsheet format, with View() (note the capital "V"):

View(airquality)

Fixing missing data

Now that we've found our missing values, what do we do with them? Well, there usually isn't a good answer, and it depends on your data and what you plan to do with it.

Removal

If you need to do something about them because your analyses require you to, the most straightforward answer is to remove them. However, if you don't have many data points or they were especially expensive or difficult to collect, you may not want to throw them away.

If we want to remove values from just one variable, we can negate the statement that we used before to find the missing values to instead return the inverse where there are no missing values, using !.

(Note: I use head() below just to avoid flooding the screen with the full data set every time. It is not required for the task.)

head(airquality[!is.na(airquality\$0zone),])

```

```

There is also a function called complete.cases() that will return only the observations that have no missing values:

```
head(airquality[complete.cases(airquality)])
```

Error in `[.data.frame`(airquality, complete.cases(airquality)): undefined columns selected Oops. I forgot to include the , after my complete.cases() expression to indicate that I'm subsetting by rows and want to keep all the columns. If I fix that, it should work:

head(airquality[complete.cases(airquality),])

```

## 150
           NA
                   145 13.2
                               77
                                       9
                                           27
```

Let's go ahead and remove all rows with any missing values from airquality and see how many rows were removed.

```
airqualityRem = airquality[complete.cases(airquality),]
nrow(airquality)
## [1] 153
nrow(airqualityRem)
## [1] 111
nrow(airquality) - nrow(airqualityRem)
## [1] 42
(nrow(airquality) - nrow(airqualityRem)) / nrow(airquality)
## [1] 0.2745098
```

We lost 42 rows, or 27.4% of the original data set. That's a pretty sizeable chunk. So, again, keep in mind what you're throwing away when you remove missing data casewise.

Replacement

Another option is replacement. Sometimes this is a good idea if you need to fix missing values by inserting the value that should have been there.

```
airqualityFix = airquality
airqualityFix[is.na(airqualityFix$0zone),][1,1] = 17
airqualityFix[is.na(airqualityFix$Solar.R),][1,2] = 142
head(airqualityFix)
##

        36
                118 8.0
## 3
        12
                149 12.6
                            74
                                   5
                                       3
## 4
        18
                313 11.5
                            62
                                   5
                                       4
## 5
        17
                142 14.3
                            56
                                   5
                                       5
                                   5
## 6
        28
                 NA 14.9
                            66
                                       6
```

Usually, though, you don't want to replace missing values with some other arbitrary value, because R won't treat them as missing values anymore.

```
airqualityRep = airquality
airqualityRep[is.na(airqualityRep) == T] = 0
head(airqualityRep)

Imputation

Another more advanced method for dealing with missing data, usually when you really need to be able to use those values for analysis, is called imputation. There are a variety of imputation methods that calculate a value to substitute in for each missing value.

One of the most basic is to use the mean of the variable:

```
airqualityImp = airquality
mean(airqualityImp$0zone, na.rm=T)
## [1] 42.12931
airqualityImp$0zone[is.na(airqualityImp$0zone)] = mean(airqualityImp$0zone, na.rm=T)
airqualityImp$0zone
##

```

Whether this is a statistically valid solution is another question. My inclination is that it's usually a bad idea. The saying goes: "garbage in, garbage out." If you're running analyses using imputed data, you can't really trust the results that come out, because your data were fabricated in the first palce. This is especially questionable if at least a third of your data are imputed. Below that, you might be able to get away with it, but I still think it's usually a bad idea.

More sophisticated imputation methods are available in the mice package.

Collinearity and confounding

Collinearity and confounding can be huge problems in your data that you should be aware of. Sometimes they're more of a theoretical concern in that they may not throw errors in your analyses, but will give you spurious results whether you're aware of them or not.

Collinearity is usually only an issue when you get to running an ANOVA or multiple regression and throw in a bunch of variables to see what best predicts some outcome variable. Collinear variables are a problem because they are highly correlated and represent the same information.

```
cor(gombe$dom, gombe$dominance)
```

```
## [1] 0.7885871
```

In the gombe data set, both of these variables represent dominance (dom is an individual attitudinal rating and dominance is a combination of several variables). If you were running analyses, you'd want to pick one and use it, not both.

Confounding is, in my opinion, one of the most important problems to understand about data, especially when you're analyzing social data.

The short definition of confounding is when you have variables that influence your predictors and your outcome, so that you think there is a relationship between your variables that is really caused by another factor.

Some good (hilarious) examples are available at: http://www.tylervigen.com/spurious-correlations

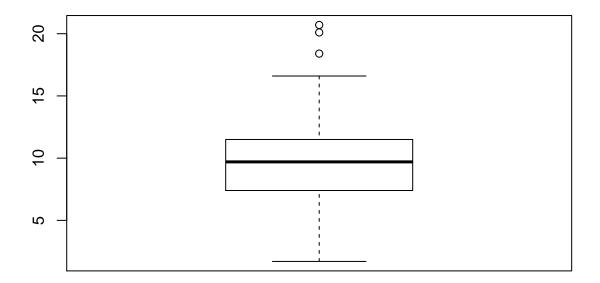

Not all of these are examples of confounding, but it's easy to imagine how some third factor might be causing the trends in both correlated variables.

A classic example is that homicide rates are highly correlated with ice cream sales. Why? Does ice cream make people kill each other? No, of course not! It's because both homicide rates and ice cream sales are higher in the summer months.

Confounding is common in social science studies when people are looking for significant relationships between social variables (like genes that cause "success"), and forget to think about things like ethnicity and socioeconomic status that are associated with many other demographic and life history variables.

Outliers

```
# windows() # Command to open a new plot window on Windows
# quartz() # Command to open a new plot window on Mac
# X11() # Command to open a new plot window on Linux
boxplot(airquality$Wind)
```

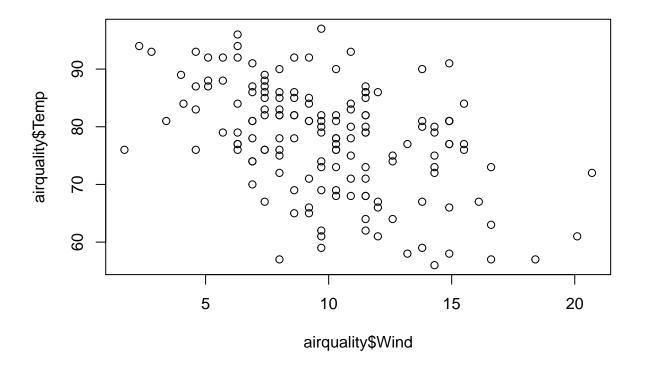

boxplot.stats(airquality\$Wind)

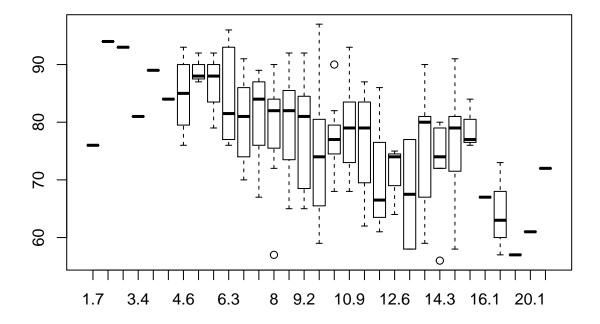

```
## $stats
## [1] 1.7 7.4 9.7 11.5 16.6
##
## $n
## [1] 153
##
## $conf
## [1] 9.176285 10.223715
##
## $out
## [1] 20.1 18.4 20.7
names(boxplot.stats(airquality$Wind))
## [1] "stats" "n"
                      "conf" "out"
boxplot.stats(airquality$Wind)$out
## [1] 20.1 18.4 20.7
```

```
"Tukey's Fences"
```

```
Quartile plus or minus 1.5 times the interquartile range:
```

boxplot(Temp ~ Wind, data=airquality)

Identifying outliers when you're looking at a distribution of more than one variable is known as multivariate outlier detection. One package that handles this is mvoutlier.

Exploratory data analysis

EDA is NOT "fishing," "data dredging," or "p-hacking." EDA is an important part of understanding your data.

                                                                   0
                                                                        0
               1
                                                         1
hist(horseKicks[,c(2:ncol(horseKicks))])
```

Error in hist.default(horseKicks[, c(2:ncol(horseKicks))]): 'x' must be numeric

Weird. Okay, let's try to coerce it to numeric.

hist(as.numeric(horseKicks[,c(2:ncol(horseKicks))]))

Error in hist(as.numeric(horseKicks[, c(2:ncol(horseKicks))])): (list) object cannot be coerced to t For some strange reason, it's stored as a list. To get it out, we can use unlist():

unlist(horseKicks[,c(2:ncol(horseKicks))])

```

                    0
```

And we can use unname() to get just the values of the vector without the column names:

horseKicksVals = unname(unlist(horseKicks[,c(2:ncol(horseKicks))]))
horseKicksVals

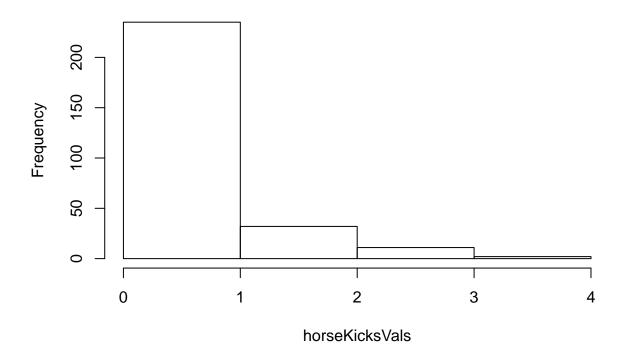

hist(horseKicksVals)

Histogram of horseKicksVals

hist(horseKicksVals, breaks=4)

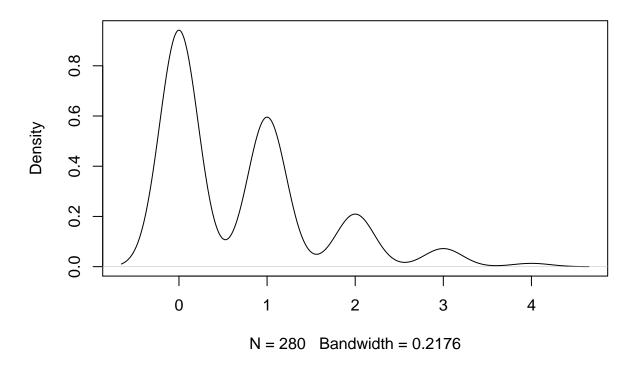

Histogram of horseKicksVals

density(horseKicksVals)

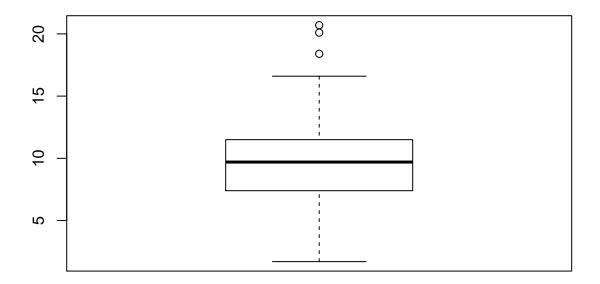

```
##
    density.default(x = horseKicksVals)
## Data: horseKicksVals (280 obs.); Bandwidth 'bw' = 0.2176
##

density.default(x = horseKicksVals)

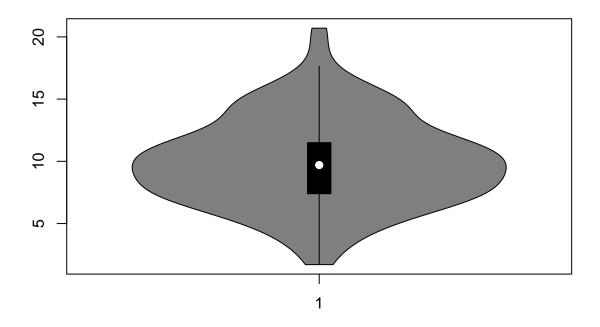

Box plots and violin plots

boxplot(airquality\$Wind)

A violin plot displays the same data, but shows the distribution of values on the horizontal (X) axis.

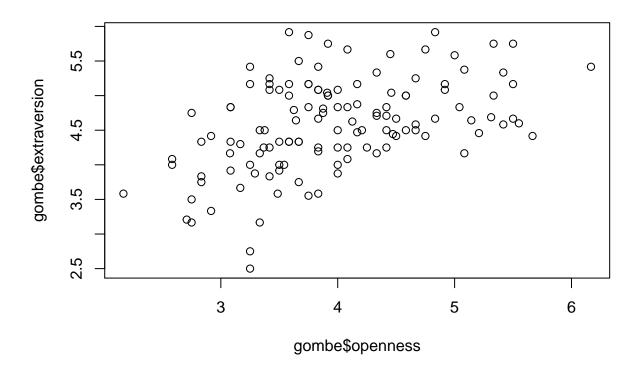

```
install.packages("vioplot")
library(vioplot)
## Warning: package 'vioplot' was built under R version 3.5.3
## Loading required package: sm
## Warning: package 'sm' was built under R version 3.5.3

## Loading required package: zoo
##
## Attaching package: 'zoo'
## The following objects are masked from 'package:base':
##
## as.Date, as.Date.numeric
vioplot(airquality$Wind)
```

Bivariate plots

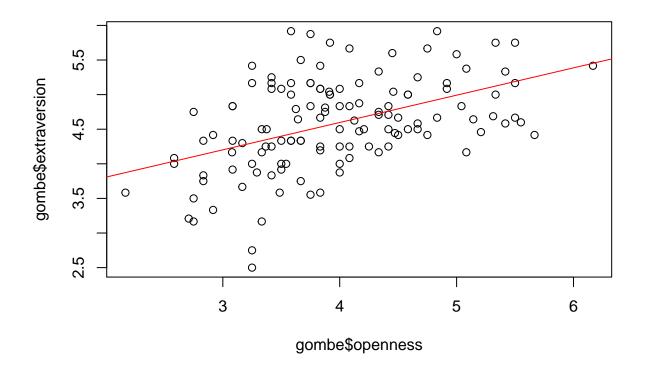

Scatterplots

plot(gombe\$openness, gombe\$extraversion)

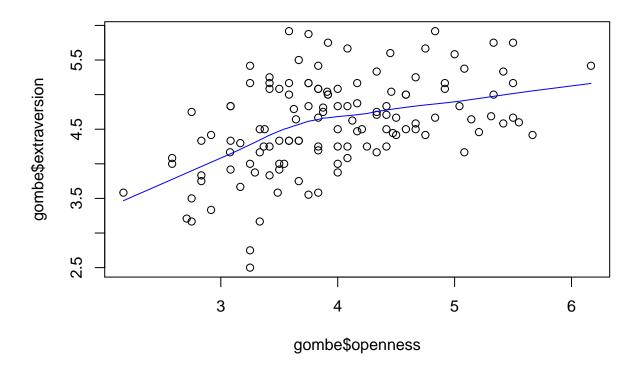

We can add a regression line:

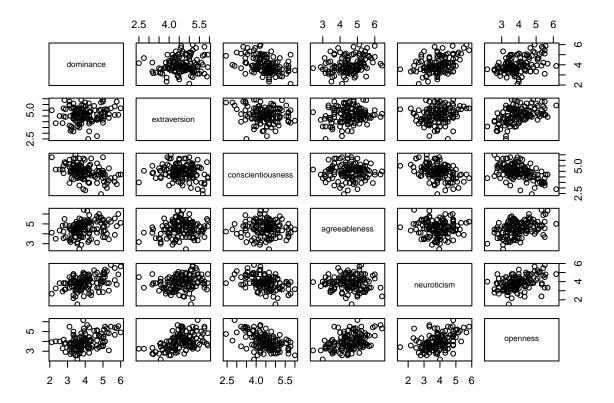

```
plot(gombe$openness, gombe$extraversion)
abline(lm(gombe$extraversion ~ gombe$openness), col="red")
```

Or a smoothed LOESS/LOWESS line:

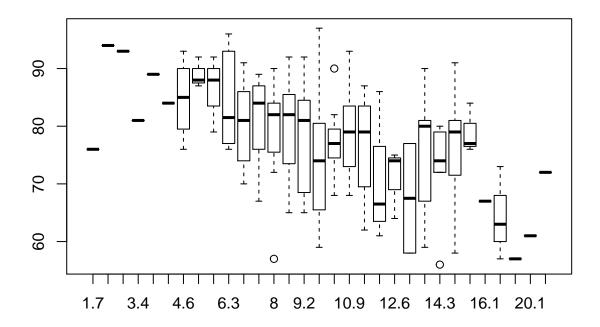

```
plot(gombe$openness, gombe$extraversion)
lines(lowess(gombe$openness, gombe$extraversion), col="blue")
```

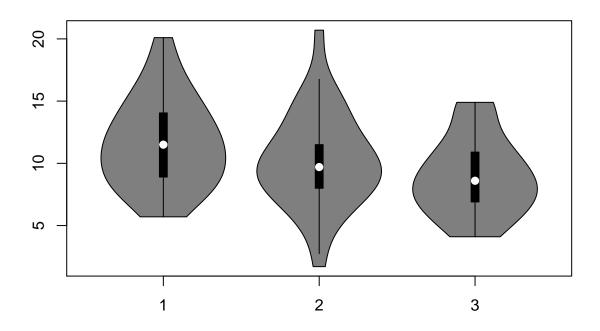

Box plots and violin plots

boxplot(Temp ~ Wind, data=airquality)

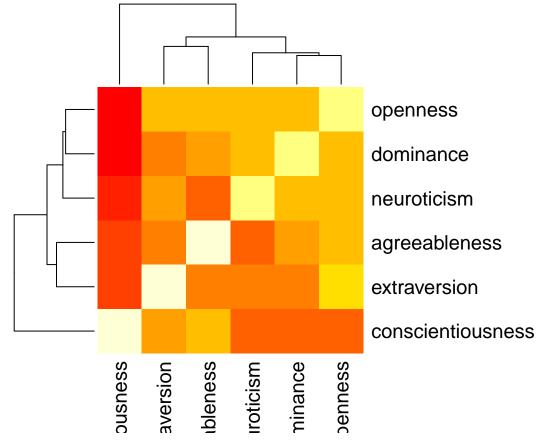

Association

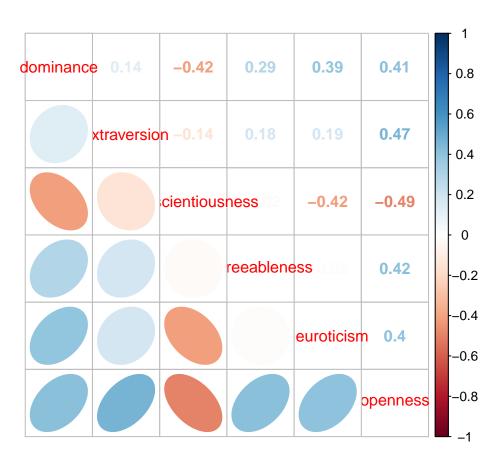

```
cor(gombe$openness, gombe$extraversion)
